Kentucky Small Grain Variety Trials 1979

W.E. Vian, V.C. Finkner and C.R. Tutt

The 1979 fall planting period was marked by good planting conditions and an excellent economic outlook for the crop. The number of acres of small grains planted in the commonwealth increased over last year's reduced acreage (Table 1) to the average for the last several years. The yield from the wheat acreage was one bu/A less than the record yield of 40.0 bu/A recorded for the 1971 crop.

Table 1.—Small Grain Harvested Acreage and Yields in Kentucky 1977-79.¹

CROP	1979		1978		1977

Rye	4	25.0	4	27.0	4	27.0

^{1/} August 10, 1979 From Crop Production, ESCS, USDA, Washington, D.C.

Small grain performance tests were conducted in six of the seven agro-climatic regions of Kentucky (Fig. 1). Agricultural areas within each region are considered to have similar soil types and climatic conditions. Each region having a substantial acreage of a small grain commodity will have a trial conducted in that region for that commodity.

Figure 1.—Agro-climatic regions of Kentucky small grain variety trials.

Region	Testing Location	Cooperator
1. Purchase	Murray	Mr. Joe Pat Caraway
2. Western Coal Field	Princeton	West Kentucky Substation
3. Ohio Valley	Henderson	Mr. Walter Gooch
4. Bluegrass	Lexington	Kentucky Agricultural Experiment Station
5. Southern Tier	Elkton	Mr. Joe Miller
6. North Central	Elizabethtown	Mr. Allen Baugh

The objective of the Kentucky small grain variety trials is to evaluate varieties of barley, wheat, and oats that are commercially available or may soon be available to Kentucky farmers. New varieties are continually being developed by agricultural experiment stations and commercial firms. Annual evaluation of small grain varieties and selections provides seedsmen, farmers, and other agricultural workers with current information to help them select the varieties best adapted to their locality and individual requirements.

Since weather, soil and other environmental factors will alter varietal performance from one location to another, tests are grown in six locations (Fig. 1) in the state (Lexington, Henderson, Elkton, Princeton, Elizabethtown, and Murray). Suggested varieties are revised each year because of the availability of new varieties, improvements in production practices, and continually changing disease and insect hazards.

EXPERIMENTAL METHODS

The plots were planted with a specially built multi-row cone seeder. Each plot consisted of four or six rows to form a plot four feet wide, which was later trimmed to 10 feet in length. Each variety was grown in four replications, and the per plot data presented are the average response from the four replications of 40 square feet harvested with a small plot combine. Planting dates of all trials for the past 3 years are listed in Table 2.

In some instances, uncontrollable factors—such as excessive rainfall, winter killing, high winds, hail, grazing cattle, etc.—adversely affected an experiment so that the results were judged unreliable. When this occurred, results are not given for that location and year. Data averaged over a period of years gives a more accurate picture of varietal performance than does annual data.

Table 2.—Planting Dates and Locations of Kentucky Small Grain Evaluation Trials 1979-77.

CROP	LOCATION AND HARVEST YEAR ¹																
	Lexington			Princeton			Murray			Henderson			Elkton			Elizabethtown

Spring Oats	3-22	3-30	3-17	-	-	-	-	-	-	-		-	-	-	-	-	-

¹The 1979 tests at Lexington, Princeton, and Henderson were planted on land not cropped the previous year. The test at Murray was planted after soybeans. The test at Elkton was planted after corn silage. The test at Elizabethtown was planted after corn for grain.

DATA COLLECTED

It is important to consider other characteristics in addition to grain yield when selecting a variety.

Grain yield of most plots was taken by cutting all rows with a self-propelled combine. The grain yields for barley and oats at Lexington and barley at Elizabethtown were taken by cutting each plot and threshing the grain with a Vogel type stationary plot thresher. The weights of each plot were recorded in grams and converted to bushels per acre.

Test weight, or the weight of a bushel of grain, is a measure of the quality of the grain. The higher the test weight, the higher the quality and market value, unless the grain has been down-graded because of another quality factor.

Lodging was recorded as the percentage of the total plants lying on the ground or leaning at a 45-degree angle from the vertical when the grain was mature. The term "maturity" as used in this report refers to the date the grain was ready to be combine harvested.

Plant height was recorded as the number of centimeters from the ground to the tip of the upright grain head, and converted to inches.

Survival was recorded as the percentage of plants estimated to have survived the winter. This is a measure of winterhardiness and is an important factor to consider when selecting a variety.

Heading date is reported as the date when 50% of the heads had emerged from the plants in each plot. This is also a measure of maturity and is important when selecting a variety for use in a double-cropping system.

Percent protein reported on a whole seed basis was measured by the Udy dye binding or near-infrared technique. Yield of grain should also be considered when evaluating protein content. The most desirable combination would be highest yield and highest percent protein. However, this combination rarely occurs. High protein content is often a result of low yield and poor grain filling seed (shriveling). Nitrogen fertilization can increase protein content of the grain.

Grams per thousand seeds is a measure of seed size and seed quality. Planting rates can be adjusted by knowing seed size. Poor quality grain is usually low in weight per thousand seeds.

Disease and insect data are reported as relative amounts that occurred on the varieties at the time the readings were made. Disease and insect problems are often different in different years.

RESULTS AND DISCUSSION

Since genetic expression of a variety is greatly influenced by environmental conditions, it is best to have several years' data from which to draw conclusions. Performance of a variety tested for only one year should not be compared with a 3-year average of another variety, since it is possible that results in one of the other years were extremely good or poor, and thus not comparable.

The yield of a variety is relative and should be compared with the yields of the other varieties in the same experiment and at the same location. Small differences in yield of only a few bushels per acre between two varieties from an individual test should not be interpreted to indicate the superiority of one variety over another. However, if one variety consistently out-yields another over a period of several years, the chances are that the differences are real.

Lodging data are very difficult to interpret. A high-yielding variety should not necessarily be down-graded because of a high percentage of lodging for a given year and at a given location. Local weather conditions, such as wind and rain, may cause a variety to lodge much more than it normally does. Variety trials normally have a greater degree of lodging than do farmer fields. It should also be emphasized that a variety reported to be 50% lodged does not imply that only 50% of the grain could be harvested. With good equipment, almost all of the grain can often be saved. Lodging data for a period of years should receive more consideration than annual lodging data since they will give a more accurate picture of varietal performance.

1979 TEST CONDITIONS

In contrast to the 1977 fall seeding weather, the 1978 fall seeding weather was near ideal. The first half of October was wet, but the latter half of October and the first half of November were mostly warm and dry, allowing good development of the small grains. The second half of November was cooler and wetter than normal. December had mild temperatures with above normal precipitation causing floods. Only a trace of snow occurred in December. January was colder and wetter than normal, averaging

almost 9 degrees below normal, making it the fifth coldest January on record. February was also colder and wetter than normal, with temperatures about 8 degrees below normal and one inch plus of precipitation above normal. December through February was the seventh coldest winter on record.

March was about 6 degrees above normal with three inches below normal precipitation. Cool wet conditions prevailed through April and May, causing the spring of 1979 to be the latest on record. Precipitation and temperature averaged above normal for the month of June. The greater than normal winter rainfall kept soils in a high moisture condition and resulted in more plant heaving damage than usual. This was true for all small grains, but was especially severe in barley. The plant heaving and colder than normal winter temperatures resulted in severe winter killing of barley and oats in some areas of the state. Winter killing of wheat was only slight (less than 5%) but the wet spring caused some localized water damage areas. Many wheat diseases occurred, but wheat spindle streak mosaic virus was the most severe infection recorded since 1974. Scab on wheat and barley was frequently observed in many fields.

The prevalence of the cereal leaf beetle continues to increase. Most plants in the spring oat test at Lexington had their flag leaves destroyed by beetle feeding.

1978 TEST CONDITIONS

The fall planting period was marked by rainy, wet soil conditions which reduced the acres planted by many small grain farmers. An early snowfall on Thanksgiving weekend stopped almost all fall small grain growth. The remainder of November and the rest of the winter months were cold. Below zero temperatures were reported in December and January with snow depths of 15 to 20 inches over most of the state. February was the coldest February on Weather Service records. Below seasonal temperatures were recorded in March and April.

Winter killing of fall seeded small grains was severe, resulting in the complete loss of some barley and oat fields. A similar winter killing occurred in our small grain breeding nursery at Lexington, with a nearly complete loss of barley and oats and even a 15%

reduction in stand of the more winter-hardy varieties of wheat. The nurseries at other locations had winter killing, but it was not as severe as that at Lexington. The reported yield of the varieties closely correlates to winter survival.

Many small grain diseases were observed, but the severity was not any greater than normal except for Scab (*Fusarium spp.*) on wheat. The variety Doublecrop had the most severe infection. Cereal leaf beetle infestation in the Lexington nurseries was the heaviest ever observed.

1977 TEST CONDITIONS

Dry soil conditions limited planting during the first half of October. The latter half of October turned cool and some precipitation occurred. Cool temperatures continued throughout the fall, resulting in very little fall growth. Many late-planted small grains did not emerge until spring. Extremely cold winter temperatures generally coincided with good snow cover on the ground except for a few days in the latter part of December. The spring growing season started with near normal soil moisture, but April, May and June were droughty in some areas of the state.

The good snow cover prevented a lot of winter killing of wheat and barley, although winter killing of oats was severe. Disease incidence was very mild or limited to localized areas. However, new strains of powdery mildew were observed, causing the "Arthur-type" wheat to be less resistant.

SMALL GRAIN VARIETIES FOR 1980

Varieties eligible for certification include (1) varieties that may have potential for Kentucky and (2) older varieties that are still acceptable for production in Kentucky. The characteristics of the small grain varieties are summarized in Tables 17 and 18.

WINTER BARLEY VARIETIES

Winter barleys are less winterhardy than winter wheat but more hardy than winter oats. The degree of winterhardiness, straw strength, and maturity are important characteristics when choosing

a variety. Varietal performance data are presented in Tables 3-6. Varieties now commonly grown are Barsoy, Monroe and Volbar. Newer varieties that show promise are Pike, Perry and Surry (see characteristics in Table 17).

SOFT RED WINTER WHEAT VARIETIES

Kentucky's climate and soils are well suited for the production of high quality soft red winter wheat. No single variety has all the desirable characteristics, but each has certain advantages. Yielding ability, straw strength, height, earliness, grain quality and disease resistance are important in choosing a variety. Varietal performance is presented in Tables 7-12. Varieties and other characteristics are listed in Table 18.

WINTER OAT VARIETIES

Winter oats are the least winterhardy of the winter grains. Early seeding, good fertilization practices, and planting on well-drained soils are recommended to minimize winter killing. Winter oats are also excellent for grazing and silage. Performance of the winter oat varieties is presented in Tables 13-15. Varieties now commonly grown are Coker 66-22, Compact, Dubois, Norline, and Walken. No released varieties appear superior to the ones commonly grown.

SPRING OAT VARIETIES

The only small grain suitable for spring seeding by farmers in Kentucky is spring oats. Spring oats are used mainly for hay or silage, and as a companion crop for grasses and legumes. Grain and forage yields of spring oats are lower than those of the winter oat varieties when yields of winter oats are not severely reduced from winter killing or disease. Two spring oat varieties (Otee and Jaycee) are commonly grown because of their higher level of resistance to Barley Yellow Dwarf Virus (oat red leaf) (Table 16).

CERTIFIED SEED

Planting certified seed is one of the first steps in ensuring a good small grain crop. The extra cost of certified seed is justified in view of the high quality of seed obtained. Certified seed is seed which has been grown in such a way as to ensure the genetic identity and purity of a variety. Certified seed also helps to maintain freedom from weed and other crop seed and, in some cases, freedom from disease. The Kentucky Agricultural Experiment Station recommends that Kentucky-certified seed be used whenever possible for growing commercial crops of small grains.

Acknowledgement is made to the University of Kentucky Computing Center for assistance in summarizing some of the results reported in this progress report; to County Agricultural Agents Ted Howard, Marvin Davidson, William Hendrick, and Jack Snyder for assistance in locating test sites and collecting data; and to Dr. Richard Stuckey for his assistance in disease identification and evaluation for the varieties at all test locations.

^{1/} Barley Yellow Dwarf Virus, mildew, and leaf rust were not evident in 1977, 1978, or 1979. Barley smuts can be controlled by planting disease-free seed so no smut data were collected. Additional data were not collected in 1979.
