

1993 Kentucky Small Grain Variety Trials

D.A. Van Sanford, C.R. Tutt,
C.S. Swanson and W.L. Pearce

In 1993, Kentucky farmers harvested 22.6 million bushels of soft red winter wheat produced on 470,000 acres. The average yield of 48 bu/a was down 7 bu/a from the yield record of 1992. Barley yields were down 2 bu/a from 1992 levels.

Small grain performance tests were conducted in six of the seven agroclimatic regions of Kentucky (Fig. 1). Agricultural areas within each region are considered to have similar soil types and climatic conditions. Each region having a substantial acreage of a small grain commodity will have a trial conducted in that region for that commodity.

The objective of the Kentucky small grain variety trials is to evaluate varieties of barley and wheat that are commercially available or may soon be available to Kentucky farmers. New varieties are continually being developed by agricultural experiment stations and commercial firms. Annual evaluation of small grain varieties and selections provides seedsmen, farmers, and other agricultural workers with current information to help them select the varieties best adapted to their locality and individual requirements.

Since weather, soil and other environmental factors will alter varietal performance from one location to another, tests are grown in six locations (Fig. 1) in the state.

Table 1—Small Grain Harvested Acreage and Yields in Kentucky, 1991-1993.*

Crop	1993		1992		1991	
	Harvest 1000 A	Yield Bu/A	Harvest 1000 A	Yield Bu/A	Harvest 1000 A	Yield Bu/A
Wheat	470	48	420	55	400	27
Barley	16	64	16	66	22	55

* July 13, 1993, Kentucky Crop and Livestock Reporting Service.

5. Southern Tier	Elkton Princeton (Limestone soil)	Andy Gray Research and Education Center	Barley, Wheat Barley, Wheat
6. North Central	Bardstown	Frankie Blanford	Wheat

Acknowledgement is made to the following individuals for their contributions to the bulletin: Ted Howard, Wayne Mattingly, Marvin Davidson and Ron Boerman, County Extension Agents for Agriculture, for assistance in locating test sites and collecting data; D. Hershman for disease ratings; K.P. Hong, P. Davidson and J. Coke for data collection; J. Byars for data analysis; R. Ring for text and table preparation.

Experimental Methods

The plots were planted with a specially built multi-row cone seeder. Each plot consisted of six rows to form a plot 4 feet wide, which was later trimmed to 10 feet in length. Each variety was grown in four replications, and the data presented are the average response from the four replications of 40 square feet harvested with a small plot combine. Planting dates of all trials for the past 3 years are listed in Table 2.

In some instances, uncontrollable factors — such as excessive rainfall, winter killing, high winds, hail, grazing cattle, etc.—adversely affected an experiment so that the results were judged unreliable. When this occurred, results are not given for that location and year. Data averaged over a period of years gives a more accurate picture of varietal performance than does annual data.

Results and Discussion

Since genetic expression of a variety is greatly influenced by environmental conditions, it is best to have several years' data from which to draw conclusions. Performance of a variety tested for only one year should not be compared with a 3-year average of another variety,

since it is possible that results in one of the other years were extremely good or poor, and thus not comparable.

The yield of a variety is relative and should be compared with the yields of the other varieties in the same experiment and at the same location. Small differences in yield of only a few bushels per acre between two varieties from an individual test should not be interpreted to indicate the superiority of one variety over another. However, if one variety consistently out-yields another over a period of several years, the chances are that the differences are real.

Lodging data are very difficult to interpret. A high-yielding variety should not necessarily be down-graded because of a high percentage of lodging for a given year at a given location. Local weather conditions, such as wind and rain, may cause a variety to lodge much more than it normally does. Variety trials normally have a greater degree of lodging than do farmer fields. It should also be emphasized that a variety reported to be 50% lodged does not imply that only 50% of the grain could be harvested. With good equipment, almost all of the grain can often be saved. Lodging data for a period of years should receive more consideration than annual lodging data since they will give a more accurate picture of varietal performance.

Table 2—Region, Location, Preceding Crop and Planting Dates of Kentucky Small Grain Trials, 1991-1993.

Region	Location	Preceding Crop	Crop	Planting Date		
				1993	1992	1991

North Central	Bardstown	1991-93	Corn	Wheat	10/21	10/16
						10/30

1993 Test Conditions

Favorable weather in early October allowed timely seeding of the wheat and barley variety trials. Mild temperatures and adequate moisture throughout the fall led to good stand establishment prior to the winter. Mild winter temperatures and continued moisture often precede heavy fungal disease pressure. This year, however, cool temperatures through May resulted in minimal fungal disease pressure. Viral disease levels, especially barley yellow dwarf virus, were quite high this year. The locations most affected by BYDV were Princeton limestone (Table 8), and Todd County (Table 8a). The Princeton limestone and the Lexington (Table 7) trials were treated with fungicides to control fungal diseases. Tests at all other locations were untreated.

Small Grain Varieties for 1994

Varieties eligible for certification include (1) varieties that may have potential for Kentucky and (2) older varieties that are still acceptable for production in Kentucky. The characteristics of the small grain varieties are summarized in Tables 3 and 11.

Soft Red Winter Wheat Varieties

Kentucky's climate and soils are well suited for the production of high quality soft red winter wheat. No single variety has all the desirable characteristics, but each has certain advantages. Yielding ability, straw strength, height, earliness, grain quality, and disease resistance are important in choosing a variety. Varietal performance is presented in Tables 4-9.

Winter Barley Varieties

Winter barleys are less winterhardy than winterwheat but more hardy than winter oats. The degree of winterhardiness, straw strength, and maturity are important characteristics when choosing a variety. Varietal performance data are presented in Tables 12-14A.

Certified Seed

Planting certified seed is one of the first steps in ensuring a good small grain crop. The extra cost of certified seed is justified in view of the high quality of seed obtained. Certified seed is seed which has been grown in such a way as to ensure the genetic identity and purity of a variety. Certified seed also helps to maintain freedom from weed and other crop seed and, in some cases, freedom from disease. The Kentucky Agricultural Experiment Station recommends that Kentucky-certified seed be used whenever possible for growing commercial crops of small grains.

CV = 10.2%	1							
LSD(0.05)=3.1 BU/A	2							

1 The CV is a measure of experimental error. The lower the CV the more reliable the results.

2 The LSD (Least Significant Difference) is the minimum difference required for two varieties to be significantly different from one another.

3 "Unauthorized propagation prohibited". Seed of these varieties must be sold by variety name only as a class of certified seed. This includes varieties for which protection has been applied and those for which protection has been granted.

¹VS=VERY SUSCEPTIBLE; R=RESISTANT; MR=MODERATELY RESISTANT
 S=SUSCEPTIBLE; MS=MODERATELY SUSCEPTIBLE;

²S=INSUFFICIENT OPPORTUNITY TO RATE IN PRESENCE OF DISEASE
 (--)=INSUFFICIENT OPPORTUNITY TO RATE IN PRESENCE OF DISEASE

In general, varieties with a VS or S reaction to a given disease will not perform well if that disease becomes severe, while varieties rated R or MR will perform well in those situations. Varieties with an MS reaction will have an intermediate response.

³RATINGS OF NEWLY RELEASED VARIETIES BASED ON 1 YR. AND 1 LOCATION

⁴BASED ON DISEASE PROGRESS AND FINAL DISEASE LEVEL

⁵BARLEY YELLOW DWARF VIRUS. * INDICATES RATINGS BASED ON TWO LOCATIONS.

CV = 10.7 % 1
LSD = 3.6 BU/A 2

1 The CV is a measure of experimental error. The lower the CV the more reliable the results.

2 The LSD (Least Significant Difference) is the minimum difference required for two varieties to be significantly different from one another.

3 "Unauthorized propagation prohibited". Seed of these varieties must be sold by variety name only as a class of certified seed. This includes varieties for which protection has been applied and those for which protection has been granted.
